The Change of Pitot Pressure across Oblique Shock Waves in a Perfect Gas

By

W. J. Graham and Miss B. M. Davis

December, 1962

1. In this note the variation of pitot pressure across an oblique shock wave in the two-dimensional flow of a perfect gas is examined by means of explicit formulae. Results are presented over the full range of shock angles for Mach numbers from 1.0 to ∞. This information is not readily available from standard references on shock wave relationships, and is given here to assist in interpreting pitot tube measurements in flows involving oblique shocks.

2. By manipulation of the usual oblique shock relations and the Rayleigh pitot formula (see for example Ref. 1) the ratio of pitot pressure across such a shock is given by

\[
\frac{P_2}{P_1} = \left( \frac{M_0^2}{M_1^2} \right)^{\frac{Y}{Y-1}} \left[ \frac{2YM_0^2 - (Y-1)}{2YM_1^2 - (Y-1)} \right] \frac{1}{Y-1} \left[ \frac{2YM_0^2 \sin^2 \theta - (Y-1)}{Y + 1} \right], \quad \ldots (1)
\]

if \( M_0 > 1 \).

The pressure, \( P \), is that indicated by a pitot tube; in supersonic flow this is the total pressure behind a normal shock; in subsonic flow it is just the stream total pressure. Suffices '1' and '2' denote conditions ahead of and behind the oblique shock respectively, \( M \) is the Mach number, \( \theta \) is the shock angle, and \( Y \) the ratio of the specific heats (assumed constant).

\( M_0 \) is related to \( M_1 \) and \( \sin \theta \) by the equation (Ref. 1)

\[
\frac{M_0^2}{M_1^2} = \frac{(Y+1)^2 M_1^4 \sin^2 \theta - 4(M_1^2 \sin^2 \theta - 1)(YM_1^2 \sin^2 \theta + 1)}{[2YM_1^2 \sin^2 \theta - (Y-1)][(Y-1)M_1^2 \sin^2 \theta + 2]} \quad \ldots (2)
\]

For the case in which \( M_0 < 1 \), the pitot pressure behind the shock is identically equal to the total pressure, and the pitot pressure ratio becomes

\[
\frac{P_2}{P_1} = \left[ \frac{\sin^2 \theta[(Y-1)M_1^2 + 2]}{(Y-1)M_1^2 \sin^2 \theta + 2} \right]^{\frac{Y}{Y-1}} \left[ \frac{2YM_0^2 - (Y-1)}{2YM_1^2 \sin^2 \theta - (Y-1)} \right]^{\frac{1}{Y-1}} \quad \ldots (3)
\]

If/

Published with the permission of the Director, National Physical Laboratory.
If $M_a$ is sufficiently large these equations become, respectively,

\[
\frac{P_2}{P_1} = \left( M_0 \right)^{y-1} \left[ \frac{2y}{2yM_0^2 - (y-1)} \right]^{y-1} \left[ \frac{2y \sin^2 \theta}{y + 1} \right], \quad \ldots \ (1a)
\]

\[
M_0^2 = \frac{(y+1)^2 - 4y \sin^2 \theta}{2y(y-1) \sin^2 \theta}, \quad \ldots \ (2a)
\]

and for $M_a < 1$

\[
\frac{P_2}{P_1} = (\csc \theta)^{y-1}. \quad \ldots \ (3a)
\]

3. Using the above relations, the ratio of the pitot pressure across an oblique shock wave in air ($y = 7/5$) has been calculated over the full range of shock angles for various Mach numbers from unity to infinity and is shown in Fig. 1. The curves to the right of the dotted line correspond to subsonic flow downstream of the shock ($M_a < 1$).

4. For the case in which $M_0 > 1$, $P_i$ is the total pressure behind the normal shock (at $M_1$) occurring at the mouth of the pitot tube; whereas $P_2$ is the total pressure behind both an oblique shock (at $M_2$) and a normal shock (at $M_0 < M_2$) again at the mouth of the pitot tube. The two-shock system leading to $P_2$ has less losses than the single shock giving $P_i$, so that $P_2$ is greater than $P_i$. As the oblique shock wave angle is decreased, for a given upstream Mach number, the strength of the oblique shock decreases and in the limit, when the shock angle equals the Mach angle, $M_2 = M_4$ and it follows, therefore, that $P_2/P_1$ is unity.

For the case in which $M_0 < 1$, $P_i$ is again the total pressure behind a normal shock at $M_1$, but $P_2$ is the total pressure behind a 'strong' oblique shock at the same Mach number. The latter shock has smaller losses and so $P_2$ is greater than $P_i$. As the oblique shock angle approaches $90^\circ$, the oblique shock becomes a normal shock and $P_2/P_1$ is again unity.

Between the two limits (Fig. 1), for which $P_2 = P_i$, the ratio $P_2/P_1$ increases to a maximum value for a given value of upstream Mach number, $M_0$. With increasing $M_0$ this peak value of $P_2/P_1$ increases, whilst the shock angle at which it occurs decreases. A limiting value of $P_2/P_1$ equal to 6 occurs at infinite $M_0$ and small $\theta$. In general, the rise of pitot pressure across an oblique shock increases with increasing Mach number for a given shock angle.

The change of pitot pressure across oblique shock waves

\[ \gamma = \frac{R_s}{R} \]

FIG. 1

[Diagram showing the variation of Pitot pressure behind shock with Shock wave angle (\( \theta \)) for different \( M_1 \) values.]
The pitot pressure behind an oblique shock wave in a perfect gas has been calculated and compared with the pitot pressure ahead of the shock. Results, for air ($\gamma = \frac{7}{5}$), are presented graphically for all shock angles and various Mach numbers from 1.0 to $\infty$.
